PROCESSED STRONG-MOTION DATA FOR
THE CENTRAL CHILE EARTHQUAKE OF MARCH 3, 1985:
FIFTEEN ACCELEROGRAPH SITES OWNED BY CHILECTRA,
ENDESA, AND THE DEPARTMENT OF GEOLOGY AND GEOPHYSICS,
UNIVERSITY OF CHILE

INTRODUCTION

The March 3, 1985 ($M_s = 7.8$) earthquake that occurred off the coast of central Chile is known to have triggered 31 accelerographs¹ located throughout the region (Fig. 1). This report presents processed records from 15 accelerographs owned and operated by CHILECTRA, Empresa Nacional de Electricidad (ENDESA), and the Department of Geology and Geophysics, University of Chile. Processed records from an additional 11 sites are presented by Celebi (1987). In addition, listings of peak accelerations from all 31 recording sites are available in Saragoni et al. (1985) and Wyllie et al. (1986).²

The mainshock occurred at 7:47 p.m. local time (22:47 UTC) on Sunday March 3, 1985. The epicenter was located off the coast of central Chile approximately 19 km west of the town of Quintay (Fig. 1). The National Earthquake Information Center (NEIC) assigned a surface-wave magnitude of $M_s 7.8$ for the mainshock, which makes it the largest earthquake to strike central Chile since 1906, when an $M_s 8.3$ earthquake occurred near Valparaíso (Comte et al., 1986). Modified Mercalli Intensities as high as IX were reported in the coastal towns of San Antonio and Llolleo (Algermissen, 1985); however, intensities ranging from VI to VIII were most common in the epicentral area (Saragoni et al., 1985).

NEIC reported the occurrence of an $m_b 5.5$ foreshock just 10.4 sec prior to the mainshock. Since the two events occurred so close in time, the Seismological Service of the Department of Geology and Geophysics, University of Chile (DGG) was able only to obtain a location for the foreshock. The earthquake parameters reported by NEIC and the University of Chile (Algermissen, 1985; Wyllie et al., 1986; Celebi, 1987) are given in the following table.

¹The accelerograph at Peldehue triggered but apparently malfunctioned.

²The San Isidro accelerograph site is mistakenly referred to as San Pedro in these two references.

Origin Time UTC	Latit- tude	Longi- tude	Depth (km)	m_b	M_s	Insti- tute
22:46:56.8	33.11°S	71.74°W	33	5.5	--	NEIC
22:46:59.9	33.24°S	71.86°W	16	--	--	DGG
22:47:07.2	33.14°S	71.87°W	33	6.7	7.8	NEIC

The depths reported by NEIC were constrained to 33 km during their computer analyses and, therefore, do not represent an accurate estimate of focal depth.

Focal mechanism studies, analyses of teleseismic recordings, geodetic measurements, and aftershock studies have led researchers to infer thrusting along the shallow-dipping interface of the Nazca and South American plates during the mainshock and many of the larger aftershocks (e.g., Dziewonski *et al.*, 1985; Comte *et al.*, 1986; Christensen and Ruff (1986); Korrat and Madariaga, 1986; Monfret and Romanowicz, 1986; Pardo *et al.*, 1986; Barrientos, 1988; Choy and Dewey, 1988). This is consistent with subduction of the Nazca plate beneath the continent of South America.

RECORDING SITES AND INSTRUMENTATION

The locations of all accelerographs that recorded the earthquake (except Peldehue) are indicated on Figure 1. The squares identify the 15 sites analyzed in this report. Coordinates, site conditions, and instrument characteristics for each site are summarized in Tables 1 and 2. Epicentral distances, peak amplitudes, and filter parameters for each accelerogram are listed in Table 3.

All but three of the recording sites were equipped with *Kinematics* SMA-1 strong-motion accelerographs. The exceptions were San Isidro and Santiago (ENDESA building), which housed *Katsujima* PK-130 accelerographs, and Rapel, where a *Teledyne* RFT-250 accelerograph was installed.

The SMA-1 and RFT-250 accelerographs are fixed-gain instruments that record acceleration on 70-mm film with a recording speed of 1 cm/sec. Nominal values for their recording sensitivity, natural frequency, and damping are 19 mm/g, 25 Hz, and 60 percent of critical, respectively. The PK-130 accelerograph is an automatic gain-ranging accelerograph that records acceleration on 90-mm light-sensitive paper with a recording speed of 5 cm/sec. The natural frequency and damping of the PK-130 accelerograph are not known; however, its frequency response is designed to be flat over the frequency range 0.3-30 Hz.

PROCESSING METHODOLOGY

Processing was performed with AGRAM, an accelerogram processing package developed by the U.S. Geological Survey (Converse, 1984). The relatively poor condition of the original film records made it necessary to digitize the recordings by hand rather than by the laser trace-following device usually used by the U.S. Geological Survey to process strong-motion records. Therefore, four AGRAM routines--IOMTAP, BUTTER, REFORM, and SCALE--could not be used in their present form and were replaced with similar routines designed to perform the same basic functions. Details of the processing steps are summarized below.

Digitization. The 70-mm film records were photographically enlarged to five times their original size to insure adequate signal-to-noise ratios. For long records, this required that the film be photographed in 100 cm frames, representing about 20 sec of record time. The frames were overlapped by about 5-10 cm during the photographic process to allow accurate reconstruction of the accelerogram after digitization. Because of the large sensitivity and fragile nature of the PK-130 recordings, they were not enlarged prior to digitization.

Each frame was digitized by means of a hand-held cursor on a digitizing table having a resolution of 0.001 in (0.00254 cm). This process resulted in a sample rate of about 250-350 samples per second and an amplitude resolution of about 0.3 cm/sec^2 (about $0.0003g$) for the film records and $0.03-0.4 \text{ cm/sec}^2$ (about $0.00003-0.0004g$), depending on the gain of the instrument, for the paper records. When possible, six traces were digitized for each accelerogram: three acceleration traces (one vertical and two horizontal components), two fixed traces, and one set of timing marks. Timing marks were written every 0.5 sec on the film records and every 0.1 sec on the paper records. There were no fixed traces on the accelerograms obtained at Colbún, Melipilla, Rapel, and Ventanas, so only the acceleration traces and timing marks were digitized for these records.

Phase I (Uncorrected Acceleration). Starting times for each trace were adjusted to minimize phasing errors and the timing trace was interpolated to determine relative time for each data point. Each trace was then adjusted to have an average amplitude of zero, after which absolute amplitudes were computed from instrument sensitivities.

Phase II (Corrected Time Series). Phase I data were interpolated to 200 samples per second, and in the case of the film records, a frequency domain instrument-correction operator was applied to remove the response of the recording system. Since the high-frequency response of the PK-130 accelerograph is flat to about 30 Hz, no instrument correction was applied to these time series.

When fixed traces were available, high-frequency noise was identified from ratios of the Fourier amplitude spectra of the acceleration and fixed traces. The ratios were plotted as a linear function of frequency to emphasize the high-frequency tail of the spectra. When fixed traces were not available, high-frequency noise was identified directly from the Fourier amplitude spectra of the

acceleration time series. High-frequency noise was removed by applying a 5 Hz bandwidth cosine taper to the Fourier amplitude spectra.

When fixed traces were available, low-frequency noise was identified from ratios of the pseudorelative velocity (PSRV) response spectra of the acceleration and fixed traces. The ratios were plotted as a logarithmic function of period to emphasize the low-frequency tail of the spectra. The filter parameter was chosen to give a minimum signal-to-noise ratio of 2:1, corresponding to signal-to-noise ratios ranging from about 3:1 to 8:1 for peak displacement. When fixed traces were not available, low-frequency noise was identified directly from the PSRV spectra of the acceleration time series. In this latter case, the filter parameter was selected to correspond to the frequency at which the presence of noise became visible on the PSRV spectra. Low-frequency noise was removed with a bidirectional (zero phase), fourth-order Butterworth filter applied in the time domain.

The PK-130 recording system applies a lowcut filter to the acceleration time series as it is recorded. As a result, the low-frequency response of this system begins to roll off at a frequency of about 0.4 Hz (2.5 sec). However, since the response of the system at 0.2 Hz (5.0 sec)--the approximate upper limit of useable signal (Table 3)--is still 85 percent of the unfiltered response, a low-frequency correction was not found to be necessary.

The instrument-corrected acceleration time series were padded with zeros, integrated, and filtered to obtain velocity. The resulting velocity records were then integrated to obtain displacement. Finally, the padded acceleration time series were filtered and unpadded to obtain corrected acceleration, velocity, and displacement.

Phase III and IV. Fourier amplitude spectra (FAS) and response spectra in terms of relative displacement (RD), relative velocity (RV), pseudorelative velocity (PSRV), absolute acceleration (AA), and pseudoabsolute acceleration (PSAA) were computed from the corrected acceleration time series at 91 periods ranging from 0.04 to 15 sec. The response spectra were calculated for five values of critical damping: 0, 2, 5, 10, and 20 percent.

Processed Data. Plots of the processed time series, Fourier amplitude spectra, and response spectra are displayed in the *Appendix*. These plots include uncorrected acceleration time series; corrected acceleration, velocity, and displacement time series; Fourier amplitude spectra, and PSRV response spectra. The plots of response spectra include both a logarithmic tripartite plot of pseudorelative velocity and a linear plot of relative velocity. The Fourier spectra are plotted as a function of both logarithmic and linear functions of frequency. On the Fourier spectra plots, F_C identifies the lowcut filter limit, F_R identifies the highcut filter limit, F_T identifies the end of the highcut filter transition bandwidth, and A_0 identifies the amplitude of the zero-frequency asymptote.

ACKNOWLEDGEMENTS

The record processing described in this report was funded jointly
by the U.S. Nuclear Regulatory Commission, the U.S. Office of Foreign
Disaster Assistance (through AID), and the U.S. Geological Survey. Dr.
Kausel's participation was partially supported by project FONDECYT-CHILE
88-1186. The accelerograms were kindly provided by the Department of
Geology and Geophysics, University of Chile; the Empresa Nacional de
Electricidad (ENDESA); and CHILECTRA. Bonny Askew provided computer
programming support during the initial phases of the study. The records
were digitized by Dean Yanacito.
